The Use of Unweighting: Clinical Applications

By

Dina Lund, P.T., A.T.C,

The Concept of Unweighting

"Unweighting is defined as applying vertical support to a patient in order to lessen weight bearing stress."

Benefits of Unweighting

- By lessening weight bearing stress
- "... allows the rehabilitation and healing of injured tissue to begin sooner utilizing task-specific functional exercises - without the pain."

Gait Deviations

- ♦ Is it a gait habit
- ♦ Soft tissue tightness
- ◆ Antalgic (painful) weight bearing
- Or are they just faking it

What Activities Can You Do Using Unweighting

- ♦ Walk, jog, run
- ♦ Sidestep, crossover
- ♦ Backpedal
- Correct spinal shift
- ♦ Step up and down
- Assist standing
- ♦ Assist sit to stand
- ♦ Balance

Potential Diagnosis

- ♦ ACL tear or reconstruction
- ♦ Any lower extremity strain or sprain
- ◆ Total knee or hip replacements
- Osteoarthritis, Rheumatoid arthritis
- ♦ Degenerative disc disease
- Spinal surgery
- Lower extremity or spinal fractures
- Neurological conditions that affect balance and gait
- Amputees (gait training or desensitization of residual limb)

Potential Factors that Influence Tolerance to Walking

- ♦ Diabetic (insensate) foot
- ♦ Obesity
- ◆ Complex regional pain syndrome (hypersensitivity)
- Poor endurance due to metabolic disease or de-conditioning
- ♦ COPD/asthma or other chronic lung conditions

The Unweighting Advantage, Why Not Use The Pool

- ♦ Cost
- Versatility
- ♦ Convenience
- ♦ Allows precise # for:
 - following orthopedic recommendations
 - documentation

The Unweighting Advantage: Why Not Use Spring or Weight Stack System

- Distributes the weight evenly over range of movement
- ♦ Air is low impact

Contraindications For Use

- ♦ Pregnant Women
- Nursing Mothers
- ♦ Obesity larger than vest can accommodate (54")
- ♦ Unstable fracture
- Caution with spondylotisthesis
- ♦ Compression aggravates condition
- ♦ Intolerance of vest
- ♦ Too uncomfortable to tolerate

What You Should Evaluate Before Using Unweighting

- ♦ Flexibility
- ◆ Strength (MMT and endurance)
- ♦ Neurological
- ♦ Balance
- ♦ Joint instability
- Gait and use of assistive devices
- Weight bearing tolerance
- ♦ Complete medical history

How To Do The Harness

- ♦ Size
- ♦ Long pants or short pants
- Avoid nylon sweat pants
- Can they stand safely to put on straps?
- ♦ Suck in air and stomach
- ◆ Tug the leg strap to tighten the opposite buttock suspension strap

Warm Up Activities

- Squat stretch
- Lateral shift corrections and extensions
- ♦ Heel cord stretch
- Hip flexor stretch

Sample Protocol: Antalgic Gait - Chronic

- Unweight to comfort for antaigia correction (generally 50-60% of body weight)
- Increase speed over session(s). (Average human gait is 3.0-4.0 M/h)
- ♦ Increase duration of workout with goal of 20-45 minutes
- Once short term duration goal is met begin decreasing unweighting by IO% of Body Weight (BW) at 5 minute intervals

Sample Protocol: Fibular Fracture - Weight Bearing as Tolerated

- Session 14, unweight to comfort (50-60% BW)
- Increase duration to 20 minutes continuous
- ◆ Increase speed each session (2-3.5 m/h over 2 4 weeks)
- ♦ Begin 5' intervals by decreasing 5- 1 0% of BW
- At 30+ minutes add slow speed agifity drills
- Agility drills should be unweighted to 50% and on "balance" mode for safety. (sidestep, backpedal, crossover)
- Incorporate speed intervals with agility drills, taper unweight at 5 minute intervals. (Est. 6 week treatment plan 2 - 4 times per week)

Sample Protocol: Acute Disc Herniation

- Unweight to comfort for first 2 weeks treatment or as needed for shift correction
- ♦ Back stretches, shift correct. May do at intervals as needed
- ◆ Increase speed each session (goal of 3-4 m/h)
- ♦ Increase duration of workout (20 45 minutes)
- At 2 weeks begin to decrease unweighting by 5-10% BW at 5' intervals
- Wean off system between 2-4 weeks as they maintain neutral spine during gait

Sample Protocol: Hemiplegia due to Cerebral Vascular Accident or Head Trauma

- Manual and thermal techniques (decrease excessive tone) prior to gait training
- ◆ Unweight % of BW to allow patient to stand with minimal assistance. "Balance" mode on unweighting system.
- ◆ Treadmill should allow as low as 5 m/h and patient must be at this pace during gait with assistive devices.
- Practice stance, weight shifts, and progress to step overs.
- Control genu recurvatum: theraband behind knee, or swiss knee cage.
- Assist dorsiflexion and hip flexion with theraband from forefoot to gait belt.
- Establish control of trunk lean and Trendefenburg gait prior to increasing speed and duration on treadmill.
